

# The central compact object in HESS J1731-347 – a new laboratory to study the equation of state and cooling mechanisms of neutron stars

D. Klochkov, V. Suleimanov, G. Pühlhofer, A. Santangelo, K. Werner (IAAT, Tübingen),  
D. G. Yakovlev (Ioffe Institute, St. Petersburg)

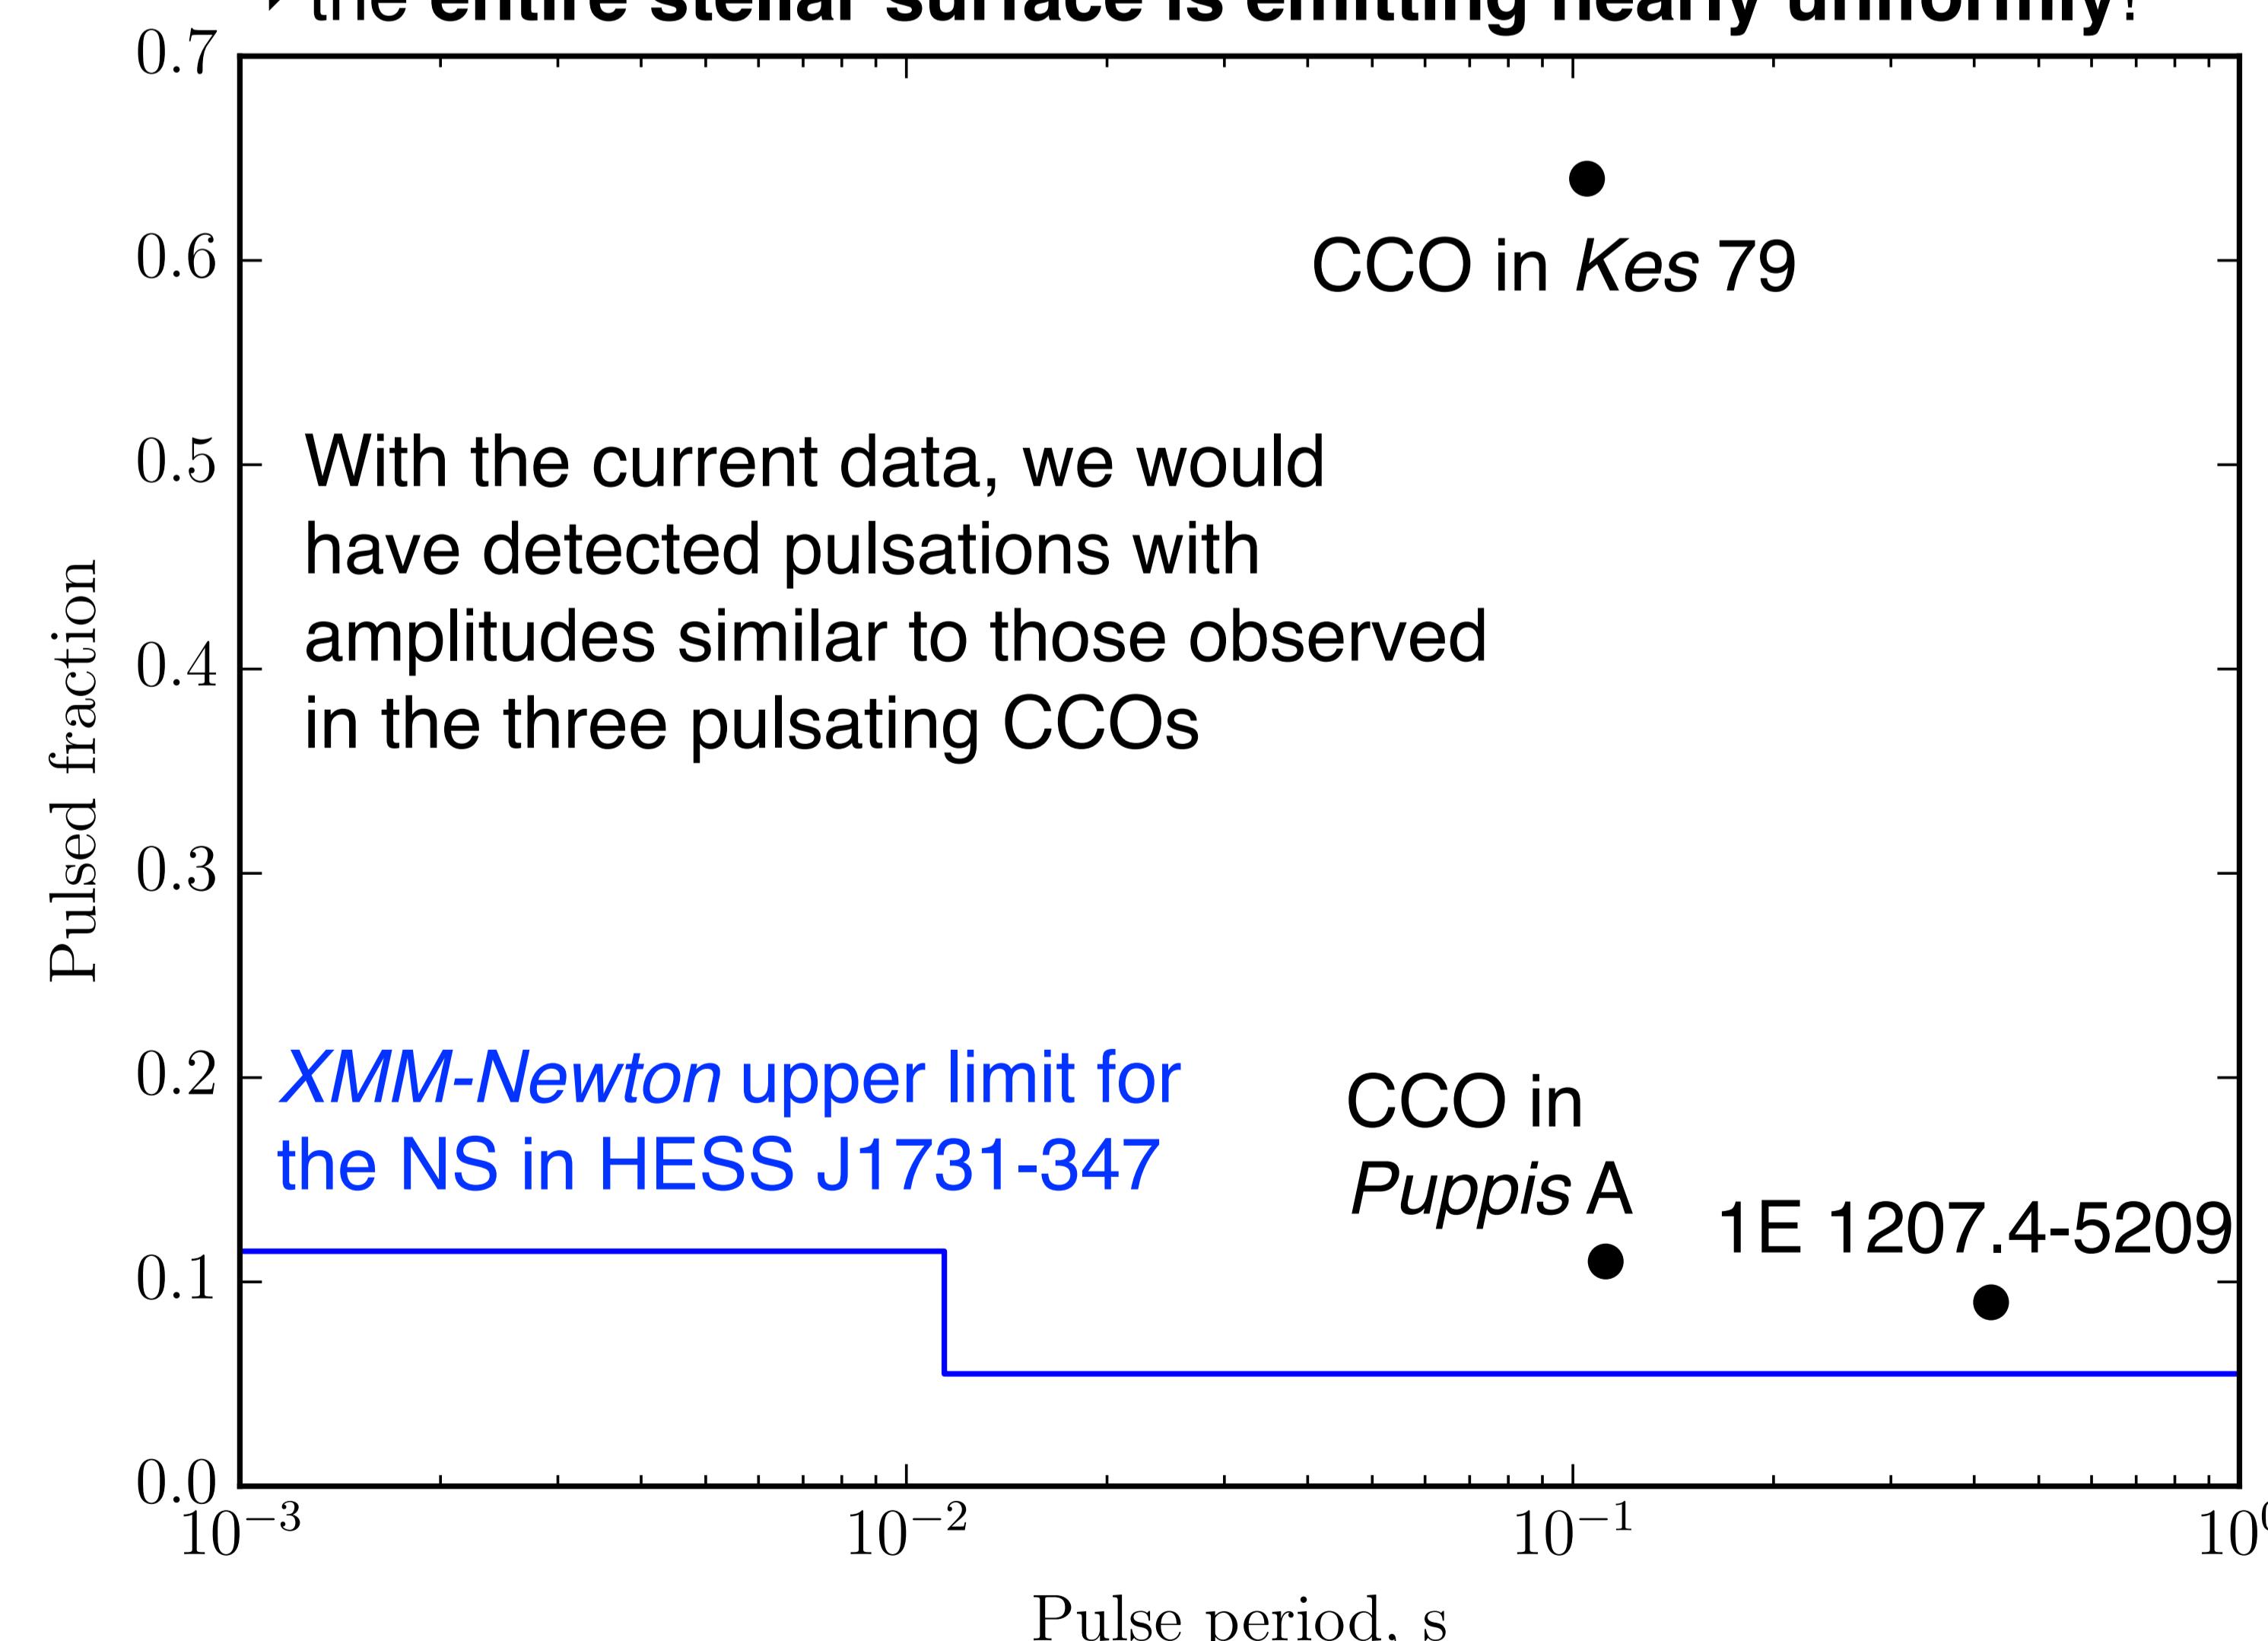

The *XMM-Newton* spectrum of the cooling neutron star in HESS J1731-347 fitted with a carbon atmosphere model

The confidence regions (solid curves) in the neutron star mass-radius plane obtained with the carbon atmosphere model and a fixed D=3.2 kpc

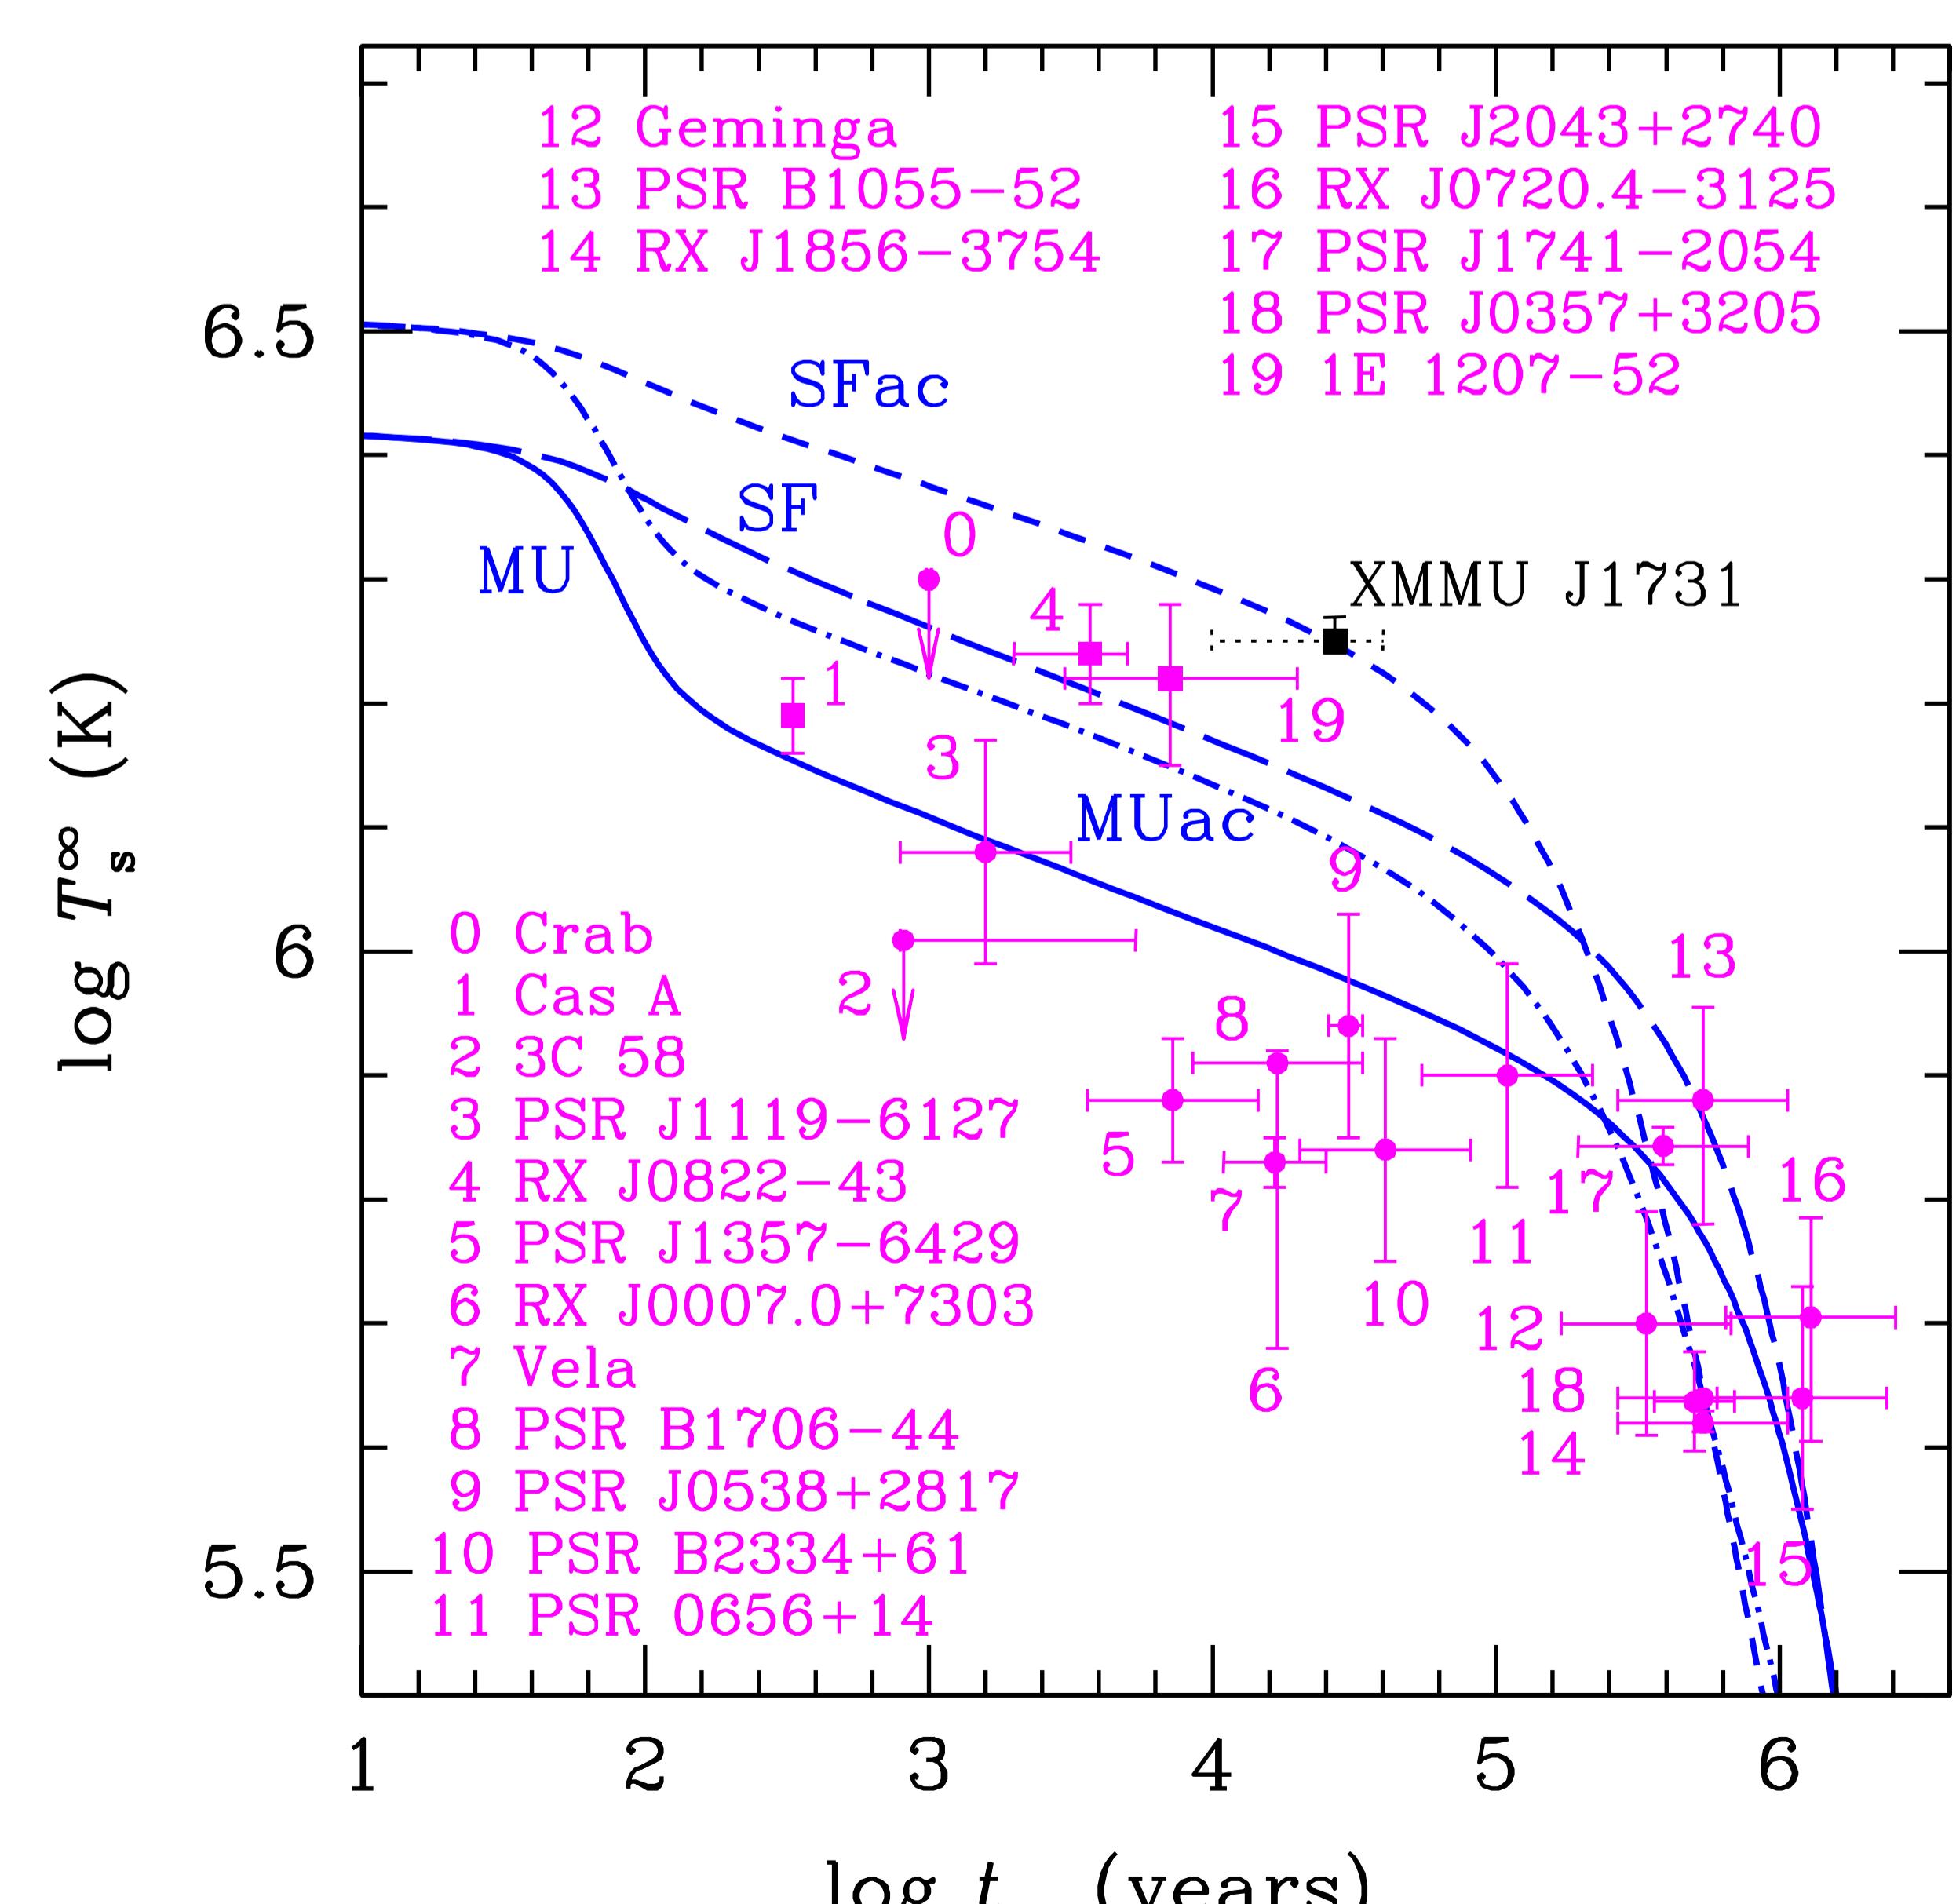

No pulsations are detected in the NS in HESS J1731-347 down to 5% pulsed fraction (see the upper limit in the picture below together with three CCOs where pulsations are detected)  
→ the entire stellar surface is emitting nearly uniformly!

Modeling of the CCO spectrum with two hydrogen models ("hot spot" + the rest of the surface) gives an area of the hot spot(s) of only ~2% of the total stellar surface → strong pulsations would be expected for such a small hot spot!

Effective surface temperatures for a number of cooling isolated NSs including the CCO in HESS J1731-347 (XMMU J1731) versus their ages compared with four theoretical cooling curves for a  $1.5 M_\odot$  star. The CCO appears exceptionally hot for an age above 10 kyr.
