→ 1st proof that the Earth is round !

7 anomalies in the sphere of the fixed stars

→ 7 days of the week :

Moon, Mars, Mercury, Jupiter, Venus, Saturn, Sun
Monday, Mardi, Mercredi, Thursday, Friday, Saturday, Sunday

Luna, Marte, Mercurio, Jupiter, Venus, Saturno, Sole
lunes, martes, miércoles, jueves, viernes, sábado, domingo.

Moving astres, called in greek $\pi\lambda\alpha\nu\eta\tau\eta\zeta$, planets.

Venus

A night sky with a bright star labeled 'Venus' and a silhouette of a hill in the foreground. The sky is dark with some faint stars visible. The hill in the foreground is dark and has a few small structures on top. The bottom of the image shows a bright orange and yellow glow, likely from a sunset or sunrise.

These celestial bodies move, but not anywhere...
One has never seen a planet in the Big Bear :

L'ÉTOILE MYSTÉRIEUSE

Planets belong to the ecliptic plane, whose intersection with the celestial sphere marks the Zodiac.

The sky in May 2007

The Solar System is flat.

The Solar System is flat, and one can see it !

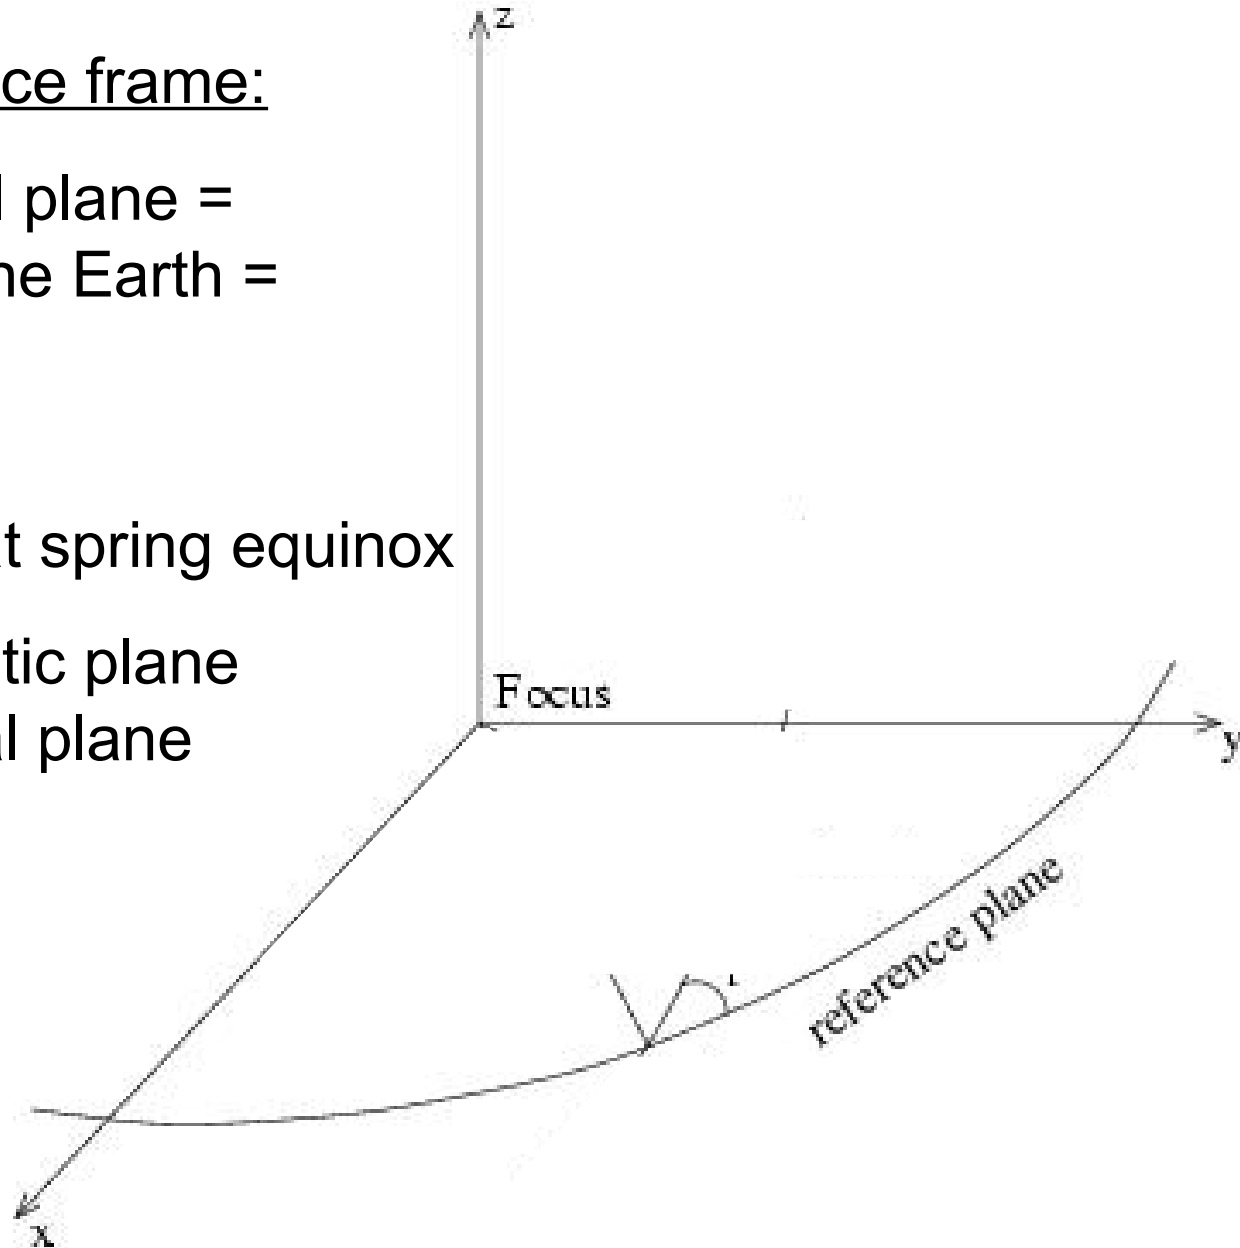

REFERENCE FRAME

Solar System reference frame:

(x,y) plane = zodiacal plane =
plane of the orbit of the Earth =
ecliptic plane

x = vernal point =
direction of the Sun at spring equinox

= intersection of ecliptic plane
and Earth's equatorial plane

ORBITAL ELEMENTS

i = inclination

Ω = longitude of the (ascending) node

ω = argument of the pericenter

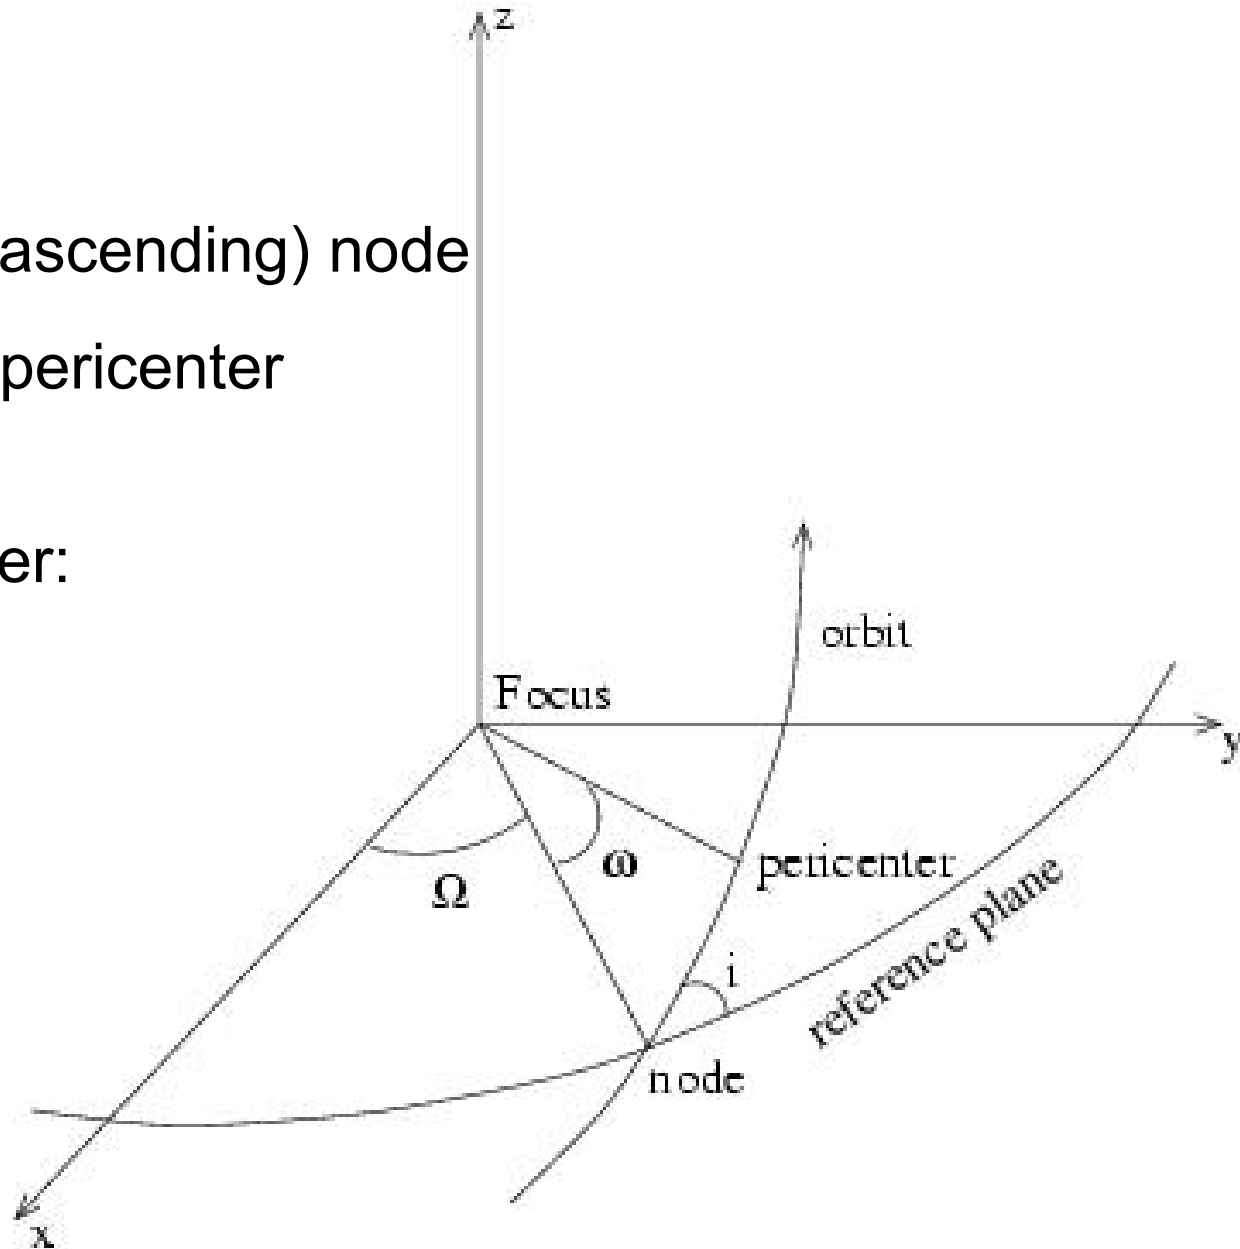

Longitude of pericenter:

$$\varpi = \omega + \Omega$$

Mean longitude:

$$\lambda = M + \varpi$$

Longitude :
angle / frame

CELESTIAL COORDINATES

Sky coordinates :

Latitude =
declination, δ .
 $\delta = +90^\circ$ above
Earth's north pole.

Longitude =
right ascension, α
from vernal point.
Given in hours :
 $24\text{h} = 360^\circ$.

Other coordinates
are possible...

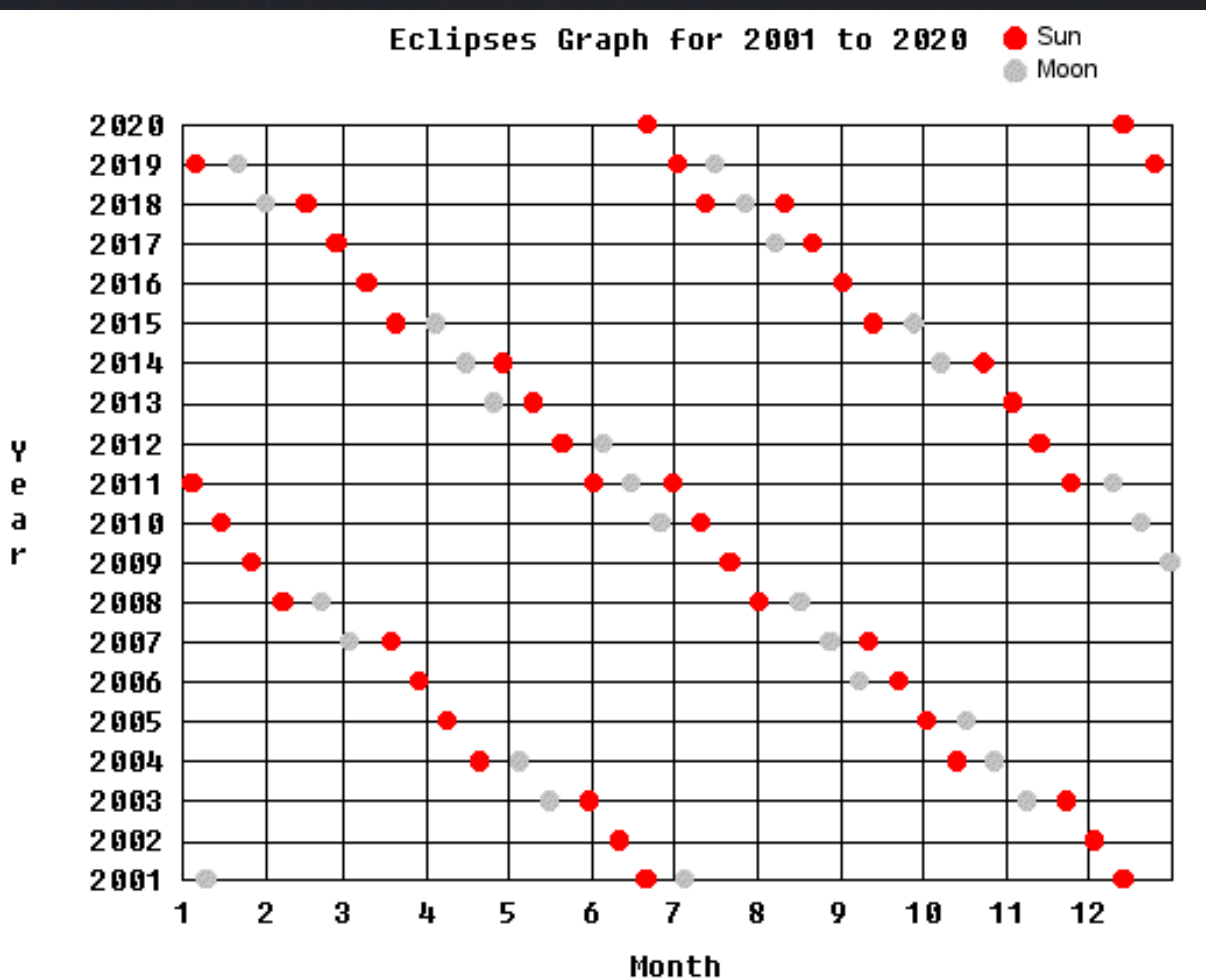

Application : the Moon has 5° inclination with respect to the ecliptic plane. It passes « above » or « below » the Sun, except when the Sun is in the line of node => eclipses !

→ Twice a year, there is a Moon eclipse, and possibly a Sun eclipse 2 weeks apart.

Application : the Moon has 5° inclination with respect to the ecliptic plane. It passes « above » or « below » the Sun, except when the Sun is in the line of node => eclipses !

→ Twice a year, there is a Moon eclipse, and possibly a Sun eclipse 2 weeks apart.

The Moon's orbital plane slowly precesses → shift of the dates year after year...

All the planes in the solar system precess :

- Earth's equator
- planet's orbits around the Sun...

The Sun has the same angular diameter as the Moon.

(Épernay, 11 / 8 / 1999)

(Sahara, Libya, 26 / 3 / 2006)

The Moon fits **3** times in the Earth's shadow (round, 2nd proof).

Exercise :

Draw the Earth,
its shadow, the
Moon, its
shadow,
respecting the
relative sizes.

→ The Moon is
4 times smaller
than the Earth.

What's the size of the Earth ?

Eratosthenes :

At the summer solstice, the Sun lits the bottom of water wells in Asswan, but is 8° from the vertical direction in Alexandria.

→ 3rd proof that the Earth is round !

Given $\alpha = 8^\circ$,

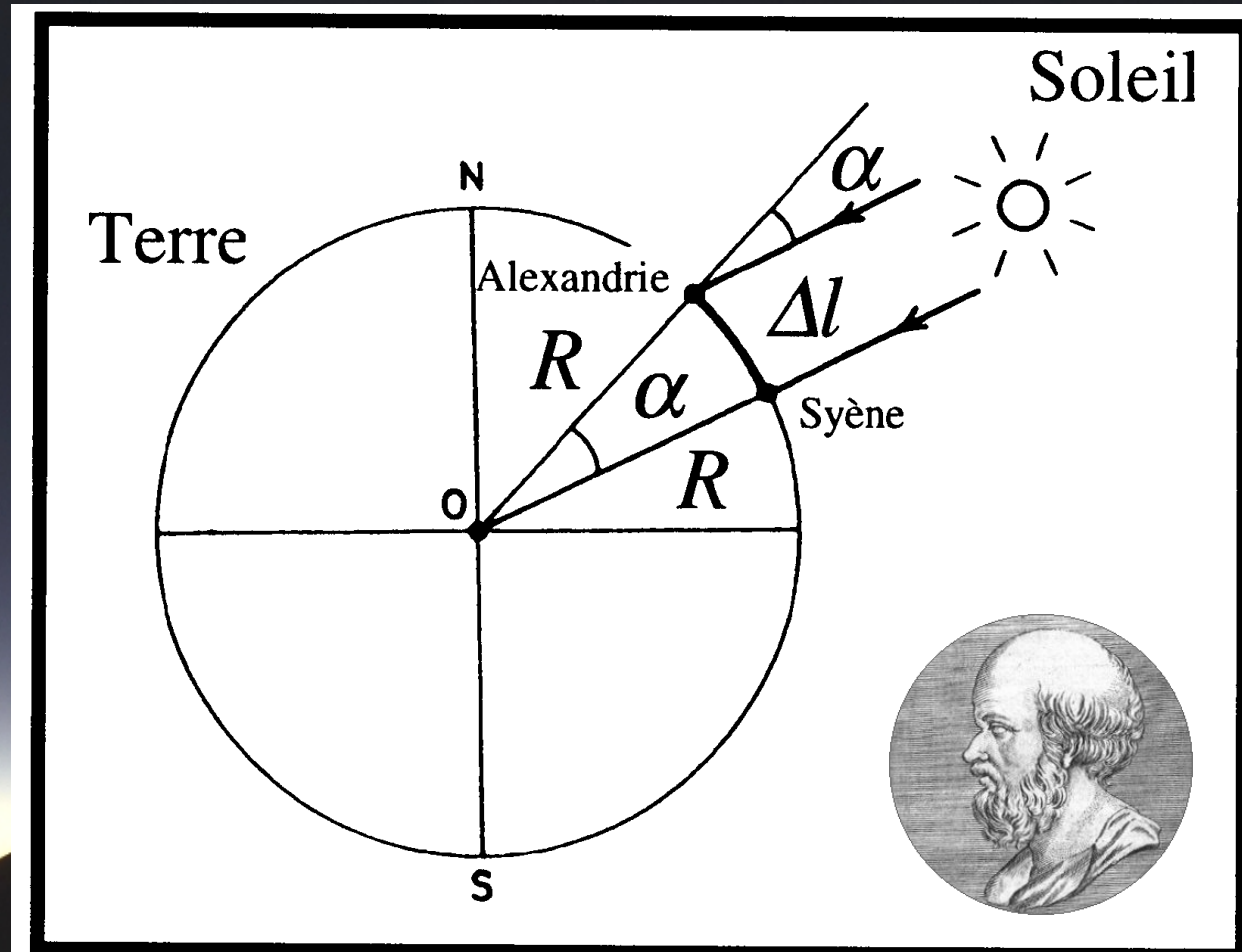

$\Delta l = 889\text{km}$,

What is the Earth's circumference ?

→ 40 000 km

Its radius ?

→ 6 400 km

At first Quarter, what can we say about the triangle EMS ?

If the angle MES is 89.85° , how far/big is the Sun ?

Solution :

There is a right angle in M.

$EM / ES = \cos(MES) = 0,0025 .$

Thus $ES = 400 \times EM.$

The Sun is 400 times further, thus larger than the Moon (as they have the same angular diameter).

Hence 100 times larger than the Earth.

The Sun is 100 times larger than the Earth,
so, the Earth should rotate around the Sun...

Alexandra Tavernier
(junior world champion, senior bronze medal)

Aristarchus of Samos
(-310 -230)

What's the distance of the Moon and Sun ?

Aristarchus again :

The Moon appears as large as 90cm stick placed 100m away (angular diameter = $0,5^\circ$).

It is 4 times smaller than the Earth (3476 km diameter), hence, according to Thales' theorem,

the Earth-Moon distance is : $3476 * 100 / 0,9 = 384\ 000\ \text{km}$.

From this, one derives the Earth-Sun distance, called the *Astronomical Unit* (reminder: TS = 390 TL) :

1 U.A. = 150 millions kilometres.

Summary :

With simple observations, a stick and a camel, we find that :

- the Solar System is flat
- the Earth is round, with a circumference of 40 000 km,
- the Moon is 4 times smaller than the Earth,
- the Sun is 100 times larger than the Earth,
- the Moon orbits around the Earth, & the Earth around the Sun.
- the Earth – Moon and Earth – Sun distances.

In spite of these obvious facts, people still voted for Donald Trump adopted Ptolemy's geocentric model of the Universe, based on Aristotle's ideas that the skies are perfect, with only circular motion, and the Earth is not pure... Earth at the centre was also promoted by the monotheisms.

Copernicus (1473-1543), conversation with God

Tycho Brahe (late XVI^e)

Danish astronomer.

His precise observations confirm that the planets orbit around the Sun.

But he suggests that the latter still orbits around a fixed Earth.

Kepler (~1600)

Deduces 3 properties of the orbits of the planets from Tycho's observations :

Three laws of Kepler (1609) :

- 1) The planetary orbits are ellipses, with the Sun in a focus, not at the centre.
- 2) A line segment joining a planet and the Sun sweeps out equal areas during equal time intervals (conservation of angular momentum)
- 3) The square of the orbital period is proportionnal to the cube of the semi-major axis (the further, the slower)

Universal gravitation (XVII°)

Isaac Newton's law of **universal gravitation** explains mathematically Kepler's 3 laws.

$$F = G M_1 M_2 / d^2$$

1781 : Discovery of Uranus, in the ecliptic plane, by chance.

1801: Discovery of Ceres → a new planet !

Then, discovery of other asteroids → asteroid belt.

1846 : Discovery of Neptune, by calculation !

1930 : Discovery of Pluto → 9th planet.!

Then, discovery of other trans-neptunian objects, a few being even larger → Kuiper belt.

We need a clear
definition of a planet.

Official definition (IAU, 2006) :

A planet is a celestial body that

- orbits around the Sun,*
- has a large enough mass so that its own gravity gives it a spherical shape (hydrostatic equilibrium),*
- dominates the local dynamics, has eliminated any other body on a nearby orbit.*

There are 8 planets in the Solar System.

If the third condition is not met : *dwarf planet*

There are 3 dwarf planets in the Solar System :
Eris, Pluto, Ceres

2007 TG422

2013 RF98

2004 VN112

2012 VP113

Sedna

2012 GB174

Planet Nine

There are 8 planets in the Solar System... + 1 ?

Some other basic definitions :

Solar System = the Sun + bodies gravitationally bound to it
(planets & their satellites, asteroids, comets, dust).
Size : ~ 1 light-year.

Star = a celestial body massive enough to make nuclear fusion,
and produce its own visible light (planets don't).

Milky Way = The Galaxy = all the stars we see in the sky,
including the white band famous as the milky way.
Size : ~ 100 000 light-years.

A galaxy = a group of billions of stars, an « island universe ».

The Universe = everything we can see with any instrument.
Size : ~ 14 billion light-years.

Light-year = distance light travels in 1 year = 10^{16} m.

MERCURY

Semi major axis : 0.387 AU.

Eccentricity : 0,2

Mass : 3.3×10^{23} kg = 0.055 of Earth

Radius : 2440 km = 38% of Earth

Density : 5 340 kg.m⁻³.

Mag field : ~Earth's field / 60.

Rotation :
spins 3 times
in 2 orbits
around the Sun.
(*resonance*)

VENUS

Semi major axis : 0.72 AU.

Eccentricity : 0,2.

Mass : 5/6 of Earth

Radius : 0.95% of Earth

Density : 5 340 kg.m⁻³.

Atmosphere : 95 Bars on the ground.

Rotation : slow (243 days) and retrograde (or inclined by 177°)

VENUS

EARTH

Semi major axis : 1 AU = 149 597 887 km.

Eccentricity : 0,016.

Rotation : sidereal period = 23h56min, inclinaison = 23,4°.

? A day = 24h ?

Mass : 6×10^{24} kg = $3 \times 10^{-6} M_{\text{sun}}$
(0.025% of which is water)

Radius : 6371 km

Density : 5 515 kg.m⁻³.

MOON

Semi major axis : 384 400 km

Eccentricity : 0.055

Mass : $\sim 1/80 M_{\text{earth}}$

Radius : $\sim 1/4 R_{\text{earth}}$

Density : $3\,344 \text{ kg}\cdot\text{m}^{-3}$.

→ very small core $< 4\%$ mass

Chemically very close to Earth's mantle (drier).

Orbital period = Rotation period =
27d 7h 43m

Time between 2 new moons
(synodic period) : 29d 12h 44m

MARS

Semi major axis : 1,52 AU.

Eccentricity : 0,09.

Rotation : period = 24h37min
inclination = 25,2°.

Mass : 6.4×10^{23} kg = 0,1 M_{earth} .

Radius : 3 390 km = 0.53 R_{earth} .

Density : 3 934 kg.m⁻³.

Water : in the polar caps + ice in the ground (permafrost).

Proofs of past water presence : hydrated minerals, canals...
Essentially lost with the atmosphere.

JUPITER

24

Semi major axis : 5,2 AU.

Eccentricity : 0,048.

Mass : 1.9×10^{27} kg = 0,001 M_{sun} .

Radius : 70 000 km.

Density : 1 327 kg.m⁻³.

Rotation : 10h,
axial tilt : 3°.

Satellites : many,
including the 4 galilean moons
Io, europa, Ganymede, Callisto.

SATURN

h

Semi major axis : 9,6 AU.

Eccentricity : 0,054.

Mass : $5.68 \times 10^{26} \text{ kg} = \sim 100 M_{\text{earth}}$.

Radius : 60 000 km.

Density : 700 kg.m^{-3} .

Rotation : 10 à 11 h,
axial tilt : 26° .

Satellites : many,
including Titan, the only
satellite with an atmosphere.

URANUS

Semi major axis : 19,2 AU.

Eccentricity : 0,047.

Mass : $8.68 \times 10^{25} \text{ kg} = 14.5 M_{\text{earth}}$.

Radius : 25 500 km = 4 R_{earth} .

Density : 1270 kg.m^{-3} .

Rotation : 17h, tilted at 98° .

Discovered by Hershell in 1781,
by chance.

NEPTUNE

Semi major axis : 30.1 AU.

Eccentricity : 0,0086.

Mass : $10,2 \times 10^{25} \text{ kg} = 17.2 M_{\text{earth}}$.

Radius : 24 600 km.

Density : 1640 kg.m^{-3} .

Rotation : 16h, tilted at 30° .

Discovered by Le Verrier in 1846,
by calulations.

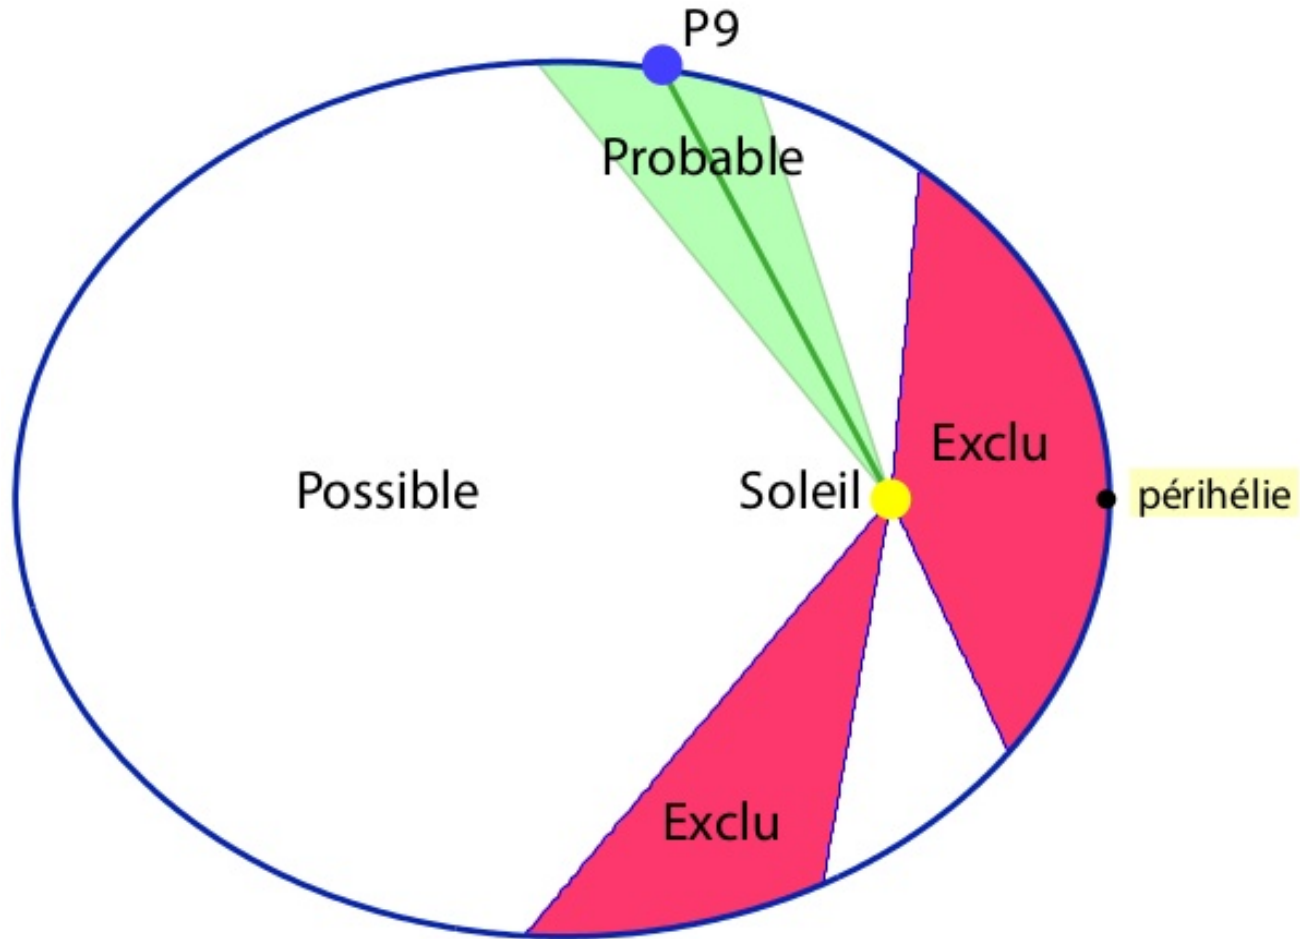

PLANET IX ?

Suggested by Konstantin BATYGIN & Mike BROWN, from the strange alignment of the orbits of KBOs.

PLANET IX ?

Tested by Agnes FIENGA & Jacques LASKAR,
from the ephemerids of Saturn.

○ Orbite de Neptune à la même échelle
